MESSAGE

Ground water utilization has increased significantly during the last two decades. The unplanned and indiscriminate use of this vital resource has resulted in declining water levels and water quality deterioration in certain areas. The apparent stress on ground water resources is more often a management issue, and this needs to be addressed in a holistic manner, for its long term sustainability, through an integrated approach. Aquifer mapping is an essential step towards the effective management of ground water resources.

The atlas entitled “Aquifer Systems of Tamil Nadu” is a step towards achieving the ultimate goal of aquifer wise management of ground water resources in Tamil Nadu State.

I congratulate Central Ground Water Board, Ministry of Water Resources for its efforts to bring out this document containing data and information pertaining to various aspects of ground water including aquifer disposition in the State. I am sure this atlas will be of immense use to planners, policy makers, researchers and users involved in ground water sector.

(Dhruv Vijai Singh)

Foreword

Availability of fresh water has always been a prime consideration in fostering the socio economic growth of the people. Rapid urbanization coupled with industrialization has resulted in increased demand of ground water at an alarming rate. Dependence on ground water is increasing continuously in order to supplement the domestic, agricultural and industrial requirements. In the last two decades there is a paradigm from development to management of Ground Water. The management of ground water is to be focussed on aquifers, which act as the repository of ground water.

To meet these challenges, it has become imperative to formulate aquifer management plan to establish the priorities for ground water use with community involvement at various levels of implementation. Central Ground Water Board over the years has generated enormous data on various aspects of ground water and has been utilised to prepare aquifer maps depicting their extent and characteristics and are compiled in the form of Atlas on "Aquifer Systems of Tamil Nadu & Puducherry".

This will provide a framework for prioritizing the aquifer level management strategies and build inventory of the aquifers for better understanding of the groundwater resources. An attempt has been made to present various aquifer systems in the form of maps by integrating all thematic information to formulate the aquifer wise ground water management plans.

The sincere efforts of the dedicated team of officers of Central Ground Water Board, South Eastern Coastal Region, Chennai is highly appreciated. I am sure this atlas would be of immense use in formulating scientifically viable implementable strategies for efficient management of ground water resources ensuring sustainability.

Preface

Groundwater is the major source of freshwater that caters the demand of ever growing domestic, agricultural and industrial sectors of the country and forms a decisive factor for sustained socio-economic development. This renewable resource has been indiscriminately exploited in some parts of the country by several users as it is easily available and reliable. On the other hand, rapid urbanization and land use changes has drastically reduced the infiltration rate into the soil and has diminished the natural recharging of aquifers by rainfall. This has lead to decline in water levels, depletion of groundwater resource and deterioration in groundwater quality. Hence, better understanding of the aquifer system is essential for proper management and effective governance of groundwater.

Central Ground Water Board (CGWB) has been pioneering, instrumental and demonstrating several scientific studies through publication of reports and maps for effective management of the aquifers. One such release is the Aquifer Atlas of Tamilnadu and Puducherry. The atlas is an amalgamation of voluminous data on the aquifer systems available in the state of Tamilnadu and UT of Puducherry. The atlas would be of immense help to the water managers, NGO's, local bodies including panchayats for proper governance of groundwater.

The efforts put by team of officers viz. Ms.D.Dayamalar, Scientist-C, Dr.M.Senthilkumar, Scientist-C, Sh.R.Arumugam, Scientist-B, Sh.N.Rameshkumar, AHG, Sh.S.P.Nayagam, Scientist-B and Dr.D.GnanaSundar, Scientist-C of South Eastern Coastal Region, Chennai is highly commendable. I am sure this aquifer atlas of Tamilnadu would form a baseline for better administration and management of the aquifer system.

INTRODUCTION

Ground water is one of the primary resources to meet the water requirements of our country. It is of vital importance for sustaining life, health & agriculture. However the distribution of availability of ground water resources across the country is uneven.

Tamil Nadu, the sixth most populous state in India is a water stressed state. The total population of the state as per 2011 Census is 7,21,38,958, of which 62 percent of the people are engaged in agriculture. Tamil Nadu state, the southern most state in the Indian Union, lies between N Latitudes 08°00' and 13°30' and E.Longitudes 76°14' and 80°18'. The state is bounded by Bay of Bengal in the east, the Indian Ocean in the south and the states of Kerala, Karnataka and Andhra Pradesh in the west, north west and north respectively with a geographical extent of 1,30,060 sq.km. It has a shoreline of about 1000 km. For administrative purposes, Tamil Nadu state is divided into 32 districts. These districts are divided into 220 taluks, which are further divided into 386 developmental blocks. These are subdivided into Panchayats representing the constituent Revenue villages and hamlets.

The Tamil Nadu state is underlain by diverse hydrogeological formations, nearly 73% of the state is occupied by hard rocks, the semi consolidated and consolidated formations are mainly confined in the eastern part which is the coastal tract. In the hard rock area, ground water is mainly developed through dug wells and dug cum bore wells tapping the weathered zone, the yield of open wells vary from 1 – 3 lps, whereas in dug wells tapping soft rocks including sedimentary formations, the yield is up to 5 lps.

Dynamic ground water resources have been assessed block-wise and during the recent resources estimation (2009), the Annual Replenishable Ground Water Resource of the state has been estimated as 22.94 bcm and Net Annual Ground Water Availability is 20.65 bcm. The Annual Ground Water Draft is 16.56 bcm and Stage of Ground Water Development is 80% leaving limited scope for further development of the dynamic ground water resources. Out of 386 assessment units (blocks), 139 have been categorized as Over-exploited, 33 as Critical, 67 as Semi-critical, 136 as Safe and 11 as Saline. Larger ground water development is noticed in the Central part of the State and it is brought out in the category map showing concentration of Overexploited and Critical block in a linear pattern extending along NE-SW direction in the Central part of the State. There has been about 6% decrease in the estimates of ground water draft in 2009 as compared to 2004. This is attributed to reduction in irrigation draft due to urbanization in some areas and reduction in usage of dugwells for domestic use. Further, recharge has enhanced in some areas because of increase in normal rainfall and enhanced activity of water conservation and canal irrigation.

The increasing stress on the limited ground water resources calls for immediate action for sustainable ground water resource management in the State. Groundwater resources available within aquifers needs to be sustainably managed with a combination of reasonable scientific knowledge, adequate monitoring and sustained political commitment and provisions for institutional arrangements. Considering the complexity of the ground water regime and the intrinsic variability of ground water systems and socio-economic situations, no single approach can fully relieve pressures on its groundwater resources. Incremental improvements in resource management and protection can, however, be achieved through suitable means. The added uncertainty of global environmental and climate change reinforces the need for sound resource management and for providing additional social and political impetus for scientific management interventions. Groundwater also needs to be considered as part of an integrated water resources management approach that co-ordinates land and water resources management, recognises water quantity and quality linkages, manages surface water and groundwater resources conjunctively and protects and restores natural systems. This integrated approach presents new challenges for groundwater management such as the need for better understanding of the effects on groundwater recharge quantity and quality of various ground water systems and many other issues.

It is in this context that systematic mapping of aquifer systems assumes great relevance in a State. Aquifer mapping is a scientific process wherein a combination of geologic, geophysical, hydrologic, and chemical field and laboratory analyses are applied to characterize the quantity, quality, and "sustainability" of ground water in aquifers. The objective of aquifer mapping is to provide critically needed information on the State's ground water for planning its sustainable development. The products of aquifer mapping studies improve our understanding of the geologic framework of aquifers, their hydrologic characteristics, water levels in the aquifers and how they change over time, and the occurrence of natural and anthropogenic contaminants that affect the quality of ground water. Results of aquifer mapping can significantly contribute to resource management tools such as long-term aquifer monitoring networks and conceptual and quantitative regional groundwater-flow models besides helping planners, policy makers and other stakeholders in taking scientifically defensible decisions.

The present aquifer mapping at Regional scale (1:250,000) forms the foundation for assessment of groundwater availability. The primary issues affecting groundwater availability vary from location to location and commonly require analysis in the context of groundwater flow systems to achieve any purposeful meaning. With this principle in mind, the studies of water balance can be taken up involving all the input and output components – rainfall, evaporation, evapotranspiration, soil moisture balance, groundwater recharge through rainfall, groundwater extraction, canal seepage, irrigation, water bodies and river-aquifer interaction etc. Multiple techniques including physical, chemical/tracer and numerical modelling approach can be used for simulating groundwater conditions and to develop aquifer management plans for optimal utilization of groundwater resources.

The aquifer mapping is of due importance in the XII five year plan. As an initiative, considering the geological and hydrologic properties of the wide array of geological formations in the state, 12 principal aquifer systems have been delineated at 1:250,000 scale. This forms the base for aquifer mapping at 1: 50,000 scale. With further inputs from the detailed Hydrogeological studies (aquifer mapping studies) in the 12th year plan, aquifer mapping can be done at cadastral level. Thus after a period of time, we shall have the status on water availability both surface and ground water and its demand at cadastral level i.e., in village wise information. This will be useful in planning/tackling at village wise. The inputs on the groundwater pollution due to natural and anthropogenic needs to be identified at cadastral level. The Atlas of aquifer mapping for the state of Tamilnadu and UT of Puducherry has enabled to have a base and to identify the data gaps, delineate the vulnerable areas and demarcate areas which may attract government intervention.

AQUIFER VULNERABLE MAP

0 50 100 kilometers

WAY FORWARD

Water is life as life do not exist where there is no water. Groundwater the nature's precious gift to the mankind easily occurs everywhere. Civilization started all along the river valleys and the development of the groundwater started from the very first day of civilization. Wherever potential groundwater was available, people dwelled around it. Further, with increase in human settlements and intensive irrigation, more stress was laid on the water bearing formations (Aquifer). Unless there is clear cut information of quantity, quality and nearness of the aquifer, the management of the aquifer is impossible.

Groundwater being a natural commodity within which life exists like air, the public has right to access the resource without fear and restrictions for their existence. At the same time the unscientific development by the affluent is a matter of concern wherein the government has to go in for groundwater governance for protecting the rights of everyone. For proper groundwater governance and management, the quantitative and qualitative distribution of groundwater is required. Aquifer mapping brings out the nature and extent of the aquifers and the availability of groundwater within the aquifers. Aquifer mapping is not about mapping the aquifers on the surface, but mapping the subsurface as well (3D disposition) which will exhibit the disposition of the aquifer, both horizontal and vertical. Aquifer systems are so different and at times complex and so as the societies that depends upon them and uses them. Ground water resources have to be conserved and utilized in an ecologically sustainable, economically efficient and socially equitable manner. Thus aquifer mapping will enable the government for judicial management of the resource so that equity is maintained between all section of people and users.

The aquifer mapping exercise integrates the existing information onto a GIS platform wherein different layers can be developed and can superimpose the layers to arrive at a solution for various groundwater management plans. The main idea behind the aquifer mapping is to go beyond the present practice of opting for a management solution based solely on the category of quantitative assessment. If aquifer wise information is available, the water managers can consult the atlas before taking decisions on various groundwater management options. A set of data on various attributes of groundwater will be available to the groundwater manager as atlas or maps and the management plans will be based on the analysis of the data or maps generated.

The aquifer mapping has brought out a strong data base by integrating the data obtained from geological, hydrogeological, hydrological, geophysical and geochemical studies. The strong data base generated for each principal aquifer in turn would facilitate in formulating aquifer management plan. Further, this has put a strong platform for micro level aquifer mapping wherein the aquifer units within the principal aquifers can be managed locally or at Panchayat level. With the availability of the aquifer maps, there can be a comprehensive assessment of the groundwater available in the state of Tamilnadu and UT of Puducherry. This can be done at appropriate scales by encompassing various administrative units like blocks, taluks and groups of Gram Panchayats overlying on an aquifer. Information of the aquifer and availability of the groundwater at Panchayat level will be crucial for sustained community action on managing groundwater.

The present aquifer mapping at Regional scale (1:250,000) forms the foundation for assessment of groundwater availability. The primary issues affecting groundwater availability vary from location to location and commonly require analysis in the context of groundwater flow systems to achieve any purposeful meaning. With this principle in mind, the studies of water balance can be taken up involving all the input and output components – rainfall, evaporation, evapotranspiration, soil moisture balance, groundwater recharge through rainfall, groundwater extraction, canal seepage, irrigation, water bodies and river-aquifer interaction etc. Multiple techniques including physical, chemical/tracer and numerical modeling approach can be used for simulating groundwater conditions and to develop aquifer management plans for optimal utilization of groundwater resources.

The aquifer mapping has been due importance in the XII five year plan. As an initiative, considering the geological and hydrologic properties of the wide array of geological formations in the state, 12 principal aquifer systems have been delineated at 1:250,000 scale. This forms the base for mapping at 1: 50,000 scale. With further inputs from the detailed Hydrogeological studies (aquifer mapping studies) in the 12th year plan, aquifer mapping can be done at cadastral level. Thus after a period of time, we shall have the status on water availability both surface and ground water and its demand at cadastral level i.e., in village wise information. This will be useful in planning/tackling at village wise. The inputs on the groundwater pollution due to natural and anthropogenic needs to be identified at cadastral level. The Atlas of aquifer mapping for the state of Tamilnadu and UT of Puducherry has enabled to identify the data gaps, delineate the vulnerable areas and demarcate areas which attract government intervention.
